Background

This looks at the severe malaria legacy dataset from MORU

Imputation of missing variables

Quite a lot of the important covariates are missing in the older studies. We use linear regression to estimate these unknown variables:

- Mising base deficit is imputed using bicarbonate (if available) else using respiratory rate
- Missing Blood urea nitrogen is imputed using creatinine

```
Impute base deficit from bicarbonate
```

```
BD_and_bicarbonate = !is.na(Leg_data$BD) & !is.na(Leg_data$bicarbonate)
print(paste('We have ', sum(BD_and_bicarbonate), 'observations for both bicarbonate and base deficit'))
## [1] "We have 5048 observations for both bicarbonate and base deficit"
mod_impute1 = lmer(BD ~ bicarbonate + (1 | studyID), data= Leg_data[BD_and_bicarbonate,])
missing_BD = is.na(Leg_data$BD)
Available_Bicarbonate = !is.na(Leg_data$bicarbonate)
print(paste(sum(missing_BD & Available_Bicarbonate), 'observations will now be imputed'))
## [1] "309 observations will now be imputed"
# impute with model
Leg_data$BD[missing_BD & Available_Bicarbonate] = predict(mod_impute1, newdata=Leg_data[missing_BD & Ava
Impute base deficit from respiratory rate
BD_and_rr = !is.na(Leg_data$BD) & !is.na(Leg_data$rr)
print(paste('We have ', sum(BD_and_rr), 'observations for both resp rate and base deficit'))
## [1] "We have 6560 observations for both resp rate and base deficit"
mod impute2 = lmer(BD ~ rr + (1 | studyID), data= Leg data[BD and rr,])
missing_BD = is.na(Leg_data$BD)
```

```
Available_rr = !is.na(Leg_data$rr)
print(paste(sum(missing_BD & Available_rr), 'observations will now be imputed'))
## [1] "2662 observations will now be imputed"
Leg_data$BD[missing_BD & Available_rr] = predict(mod_impute2,newdata=Leg_data[missing_BD & Available_rr
Impute blood urea nitrogen from creatinine:
BUN_and_cr = !is.na(Leg_data$BUN) & !is.na(Leg_data$creatinine)
print(paste('We have ', sum(BUN_and_cr), 'observations for both blood urea nitrogen and creatinine'))
## [1] "We have 1433 observations for both blood urea nitrogen and creatinine"
mod_impute3 = lmer(BUN ~ creatinine + (1 | studyID), data= Leg_data[BUN_and_cr,])
missing_BUN = is.na(Leg_data$BUN)
Available_cr = !is.na(Leg_data$creatinine)
print(paste(sum(missing_BUN & Available_cr), 'observations will now be imputed'))
## [1] "679 observations will now be imputed"
Leg_data$BUN[missing_BUN & Available_cr] = predict(mod_impute3,newdata=Leg_data[missing_BUN & Available
Resulting data we can now use: The contributions of the different studies:
vars_interest = c('outcome','HCT','LPAR_pct','BD','BUN','poedema','convulsions','coma','AgeInYear','dru
complete_cases = apply(Leg_data[,vars_interest], 1, function(x) sum(is.na(x))) == 0
Complete_Leg_data = Leg_data[complete_cases,] # for the model fitting
Complete_Leg_data$studyID = as.factor(as.character(Complete_Leg_data$studyID))
# Whole dataset

Now let's make counterfactual predictions of anaemia on death for the patients in the database.
myquantiles = c(0.25, 0.5, 0.75) # this is 50% predictive interval
overall_median_mortality = median(100*predict(mod_full, type='response'))
par(las=1, bty='n')
x_hcts = seq(4,45, by=1)
probs_lin = array(dim = c(3, length(x_hcts)))
for(i in 1:length(x_hcts)){
 mydata = Complete_Leg_data
 mydata$HCT=x_hcts[i]
 ys = 100*predict(mod_full, newdata = mydata, re.form=NA, type='response')
 probs_lin[,i] = quantile(ys, probs=myquantiles)
```

3618.6 -1761.4

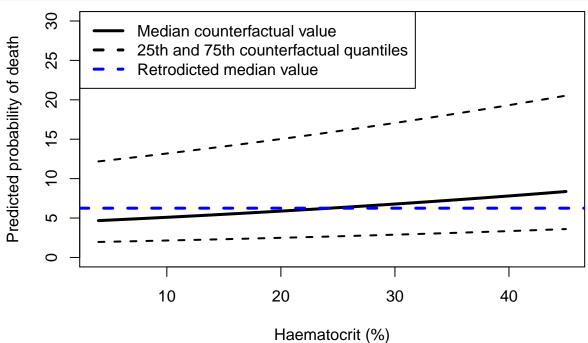

3522.7

6086

##

3544.7

The way to interpret this 'counterfactual' plot is as follows: suppose that every individual in the dataset was assigned (as in a intervention) a specific haematocrit X, what would the resulting per patient probability of death be. Here we summarise these probabilities by the predicted mean probability of death and 80% predictive intervals.

More complex GAM model

Link function: logit

Parametric coefficients:

The GAM model allows for non-linear relationships between certain variables and the outcome.

Here we fit as non-linear the effect of age and haematocrit on mortality.

```
##
## Formula:
## outcome ~ s(HCT, AgeInYear) + LPAR_pct + coma + convulsions +
## poedema + BUN + BD + drug_AS
##
```

```
##
             Estimate Std. Error z value Pr(>|z|)
## (Intercept) -4.382411 0.125428 -34.940 < 2e-16 ***
## LPAR_pct
             1.393212 0.096148 14.490 < 2e-16 ***
## coma
## convulsions1 0.514489 0.111133
                              4.629 3.67e-06 ***
## poedema1 0.735753 0.363146 2.026 0.042759 *
## BUN
            0.013112 0.001594 8.227 < 2e-16 ***
             ## BD
## drug_AS
           ## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Approximate significance of smooth terms:
                 edf Ref.df Chi.sq p-value
## s(HCT,AgeInYear) 6.936 9.685 97.96 <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## R-sq.(adj) = 0.251 Deviance explained = 26.6%
## UBRE = -0.4212 Scale est. = 1
```

Now we compute the corresponding counterfactual probabilities of death for the dataset for all values of the haematocrit:

```
overall_median_mortalityGAM = median(100*predict(mod_full_GAM, type='response'))
par(las=1, bty='n')
probs_gam = array(dim = c(3, length(x_hcts)))
for(i in 1:length(x_hcts)){
   mydata = Complete_Leg_data
   mydata$HCT=x_hcts[i]
   ys = 100*predict(mod_full_GAM, newdata = mydata, re.form=NA, type='response')
   probs_gam[,i] = quantile(ys, probs=myquantiles)
}
```

We see that the effect of haematocrit on mortality is non-linear under this model: below 20 is protective, above 20 plateaus out:
